Summary:
Comparisons of individual DNA-profiles between different laboratories require that the data can be standardized. In this study, we compared DNA profiles of brown bears (*Ursus arctos*) from Sweden with DNA profiles of Norwegian brown bears. Brown bear samples from Sweden were analyzed at Laboratoire d'Ecologie Alpine (LECA) in France, while the samples collected in Norway were analyzed in the DNA laboratory at Bioforsk Svanhovd. In April 2008, DNA from 38 different bears were analyzed both at LECA in France and at Bioforsk Svanhovd in Norway, which allowed to estimate a first calibrations keys and normalise the data. In this study, new calibration keys were determined in order to make the genotypes from Norwegian bears comparable with the whole Swedish bear genetic database. The comparison based on the new calibration key included 163 individuals from Norway (time period 2005-2009) and gave 42 matches with individuals from the database for Swedish brown bears (time period 2001-2009). Marker MU59 did not function well in this calibration and additional analyses are needed to sort out the problems with this marker.

Sammendrag:
Sammenligning av individuelle DNA-profiler mellom ulike laboratorier krever at data kan bli standardisert. I dette studiet sammenlignet vi DNA profiler av brunbjørn (*Ursus arctos*) fra Sverige med DNA profiler av brunbjørn i Norge. Prøver fra brunbjørn samlet i Sverige ble analysert ved Laboratoire d'Ecologie Alpine (LECA) i Frankrike mens prøver samlet i Norge ble analysert i DNA laboratoriet ved Bioforsk Svanhovd. I april 2008 ble DNA fra 38 bjørneindivider analysert både ved LECA i Frankrike og Bioforsk Svanhovd i Norge, noe som gjorde det mulig å estimere et første sett med kalibreringsnøkler og deretter normalisere data. I dette studiet, nye kalibreringsnøkler ble bestemt for å gjøre genotyper fra norske bjørner sammenlignbare med databasen for brunbjørn i Sverige. Sammenligningen basert på de nye kalibreringsnøklerne inkluderte 163 individer fra Norge (tidsperiode 2005-2009) og gav 42 match med individer fra databasen for brunbjørn i Sverige (tidsperiode 2001-2009).

Markøren MU59 fungerte ikke i denne kalibreringen, og tilleggsanalyser er nødvendig for å løse problemet med denne markøren.

1. Abstract

Comparisons of individual DNA-profiles between different laboratories require that the data can be standardized. In this study, we compared DNA profiles of brown bears (*Ursus arctos*) from Sweden with DNA profiles of Norwegian brown bears. Brown bear samples from Sweden were analyzed at Laboratoire d'Ecologie Alpine (LECA) in France, while the samples collected in Norway were analyzed in the DNA laboratory at Bioforsk Svanhovd. In April 2008, DNA from 38 different bears were analyzed both at LECA in France and at Bioforsk Svanhovd in Norway, which allowed to estimate a first calibrations keys and normalise the data. In this study, new calibration keys were determined in order to make the genotypes from Norwegian bears comparable with the whole Swedish bear genetic database. The comparison based on the new calibration key included 163 individuals from Norway (time period 2005-2009) and gave 42 matches with individuals from the database for Swedish brown bears (time period 2001-2009).

Marker MU59 did not function well in this calibration and additional analyses are needed to sort out the problems with this marker.

2. Introduction

The population of brown bears (*Ursus arctos*) in Sweden has increased from a small remnant population of 130 individuals in 1930 (Swenson et al. 1995) to a population of more than 2500 individuals at present (Sahlén et al. 2006). Since the 1990s, Taberlet and his colleagues at the Laboratoire d'Ecologie Alpine (LECA) in France have used DNA analyses to investigate the Swedish brown bear population (Taberlet et al. 1995). In Norway, the brown bear was eliminated by 1930 due to human persecution, but at present Norway has a population of more than 120 individuals, and during the last 5 years more than 230 individuals have been identified (Eiken et al. 2007, 2009, Bjervamoen et al. 2008a, Warttinen et al. 2008, 2009). These individuals have been identified through DNA analysis of brown bear fecal and hair samples (collected 2004-2008) at the laboratory at Bioforsk Svanhovd in Norway. A comparison of individual DNA-profiles between Norwegian and Swedish brown bears is of major interest to both research and management. However, the two laboratories have minor differences in methods and equipment, and e.g. electrophoretic conditions may affect mobility of DNA fragments and size determination of STR alleles. Thus, normalization of allele sizes using a set of size standards will be required to perform interlaboratory comparisons (Budowle et al. 2005).

In 2008, a set of calibration keys were calculated for 6 microsatellite markers (Mu10, Mu23, Mu50, Mu51, Mu59 and G10L) based on DNA analysis of 38 brown bear individuals from North-Norway. DNA from the 38 individuals were analyzed both at LECA in France and at Bioforsk Svanhovd. Results from this calibration and later comparison with analysis of brown bears from mid-Norway and Jämtland 2006, have been reported previously (Poillot et al., Report from Laboratoire d'Ecologie Alpine, April 2008, Bjervamoen et al. 2008b).

In 2009, genotypes from 79 brown bear individuals from South-Norway calibrated according to results from 2008 were compared with the genotypes in the database for Swedish brown bears. The initial comparison gave no match, even for individuals analyzed at both laboratories (HE29 and HE59). A meeting at Svanhovd 23.-25 September 2009 between (Eva Bellemain, from) LECA and (Siv Grete Aarnes and Ingvild Warttinen from) Bioforsk Svanhovd was arranged with the aim to identify problems and suggest solutions. In this study, we describe the results of a novel normalization of the data and the subsequent search in the Swedish database with 163 DNA profiles/individuals from Bioforsk Svanhovd.

3. Methods

Calculation of new calibration keys

At LECA, because of changes and upgrades in sequencing machines, three internal calibration keys have been used, i.e, a first one for the data produced before 2004, a second one for the years 2004-2006 and a third one from the year 2007 (that we name 2007-2009 hereafter).

The database from Swedish brown bears was standardized based on the 2004-2006 data, which means that all genotypes have been recalibrated to be comparable with the data from 2004-2006.

In 2008, 38 individuals of brown bear from North-Norway were analyzed at LECA to calculate calibration keys for genetic profiles for comparing data between LECA and Svanhovd. At this point the internal calibration was not yet done at LECA and the calibration keys were based on the 2007-2009 data (see also Bjervamoen et al. 2008b). Therefore it was not possible to compare genotypes from South-Norway bears with genotypes from the calibrated database of Swedish bears. The calibration keys for LECA and Svanhovd data was then revised using the internal calibration key of Swedish data of 2007-2009 versus 2004-2006 on the same 38 individuals (see Appendix 1).

Comparison of genotypes

After the new calibration of genotypes of Norwegian brown bears, we used a python script (J. Bessi re, 2009, unpublished) to compare the Norwegian and Swedish bear genotypes. The comparison included a total of 163 different Norwegian brown bear individuals (Appendix 2), registered from 2005 until September 2009 in the Genetic database at Bioforsk Svanhovd. The individuals HE53, HE56, TR13, ST4, ST8, ST9, ST10 and ST11 were not included in the search. The Swedish database included DNA profiles of 6123 samples from the time period 2001 until 2009.

The principle of this script is to group samples as individuals based on 6-loci genotypes, allowing 1 allele mismatch as well as a maximum of 2 missing alleles. Each sample ID is given a genotype ID number as well as an individual ID number (gen id and ind id in Appendix 2).

The script output file was checked manually, selecting only the individual IDs that included Norwegian sample IDs. We considered field data (sampling date, death date, coordinates) as well as genotyping data (number of alleles compared, sex, type of mismatches) to confirm or exclude a match.

When considering mismatches, we accepted matches with mismatch types corresponding to potential allelic dropouts but we excluded matches with mismatch types corresponding to alleles that were too different from each other.

4. Results and discussion

Calibration keys for the microsatellites

The calibration keys between LECA and Bioforsk Svanhovd calculated in 2008 (Bjervamoen et al., 2008b) were revised based on the 2004-2006 internal calibration from LECA to enable comparison of results between the two laboratories (see Method section and appendix 1)

The revised calibration key for the six microsatellites included in this study is shown in Table 1.

Table 1: Calibration keys for microsatellites and their known alleles, labs at Svanhovd and LECA.

Marker	Calibration key (difference in base pair) Svanhovd/LECA 2004-2006	Notes
Mu10	19	
Mu23	21	
Mu50	27	
Mu51	24	
Mu59	132/134?	Uncertain, the differences were not consistent.
G10L	30/32	Allele 170 and 172 (Svanhovd) have calibrations key 32.

LECA uses automatic reading in the genotyping work, while the laboratory at Bioforsk Svanhovd uses manual reading in the genotyping. Those different methods will in some cases generate differences in sizing of the alleles (Bjervamoen et al., 2008b). The differences in allele-sizing between the two laboratories were consistent, and determination of calibrations keys were possible, but some markers may have more than one key (G10L-see table 1). The alleles analyzed so far are shown in appendix 1. All new alleles need to be analyzed at both labs.

The difference between single alleles of the MU59 marker was not consistent; therefore the calibration key for this marker is uncertain. The reason is unclear and additional DNA analyses are necessary to solve this issue.

Consequently, to avoid problems in the comparison of genotypes, the problematic MU59 alleles for Norwegian bears were set to 0 (missing data) before performing the comparison of genotypes. We only kept the alleles that were judged as reliable (always consistent in the comparisons and the matching), i.e. alleles 94, 96 and 108 (see appendix 2). Consequently, the comparison was mainly based on 5 markers. To help confirming or excluding matches, as a post-treatment to the output, we manually added possible Mu59 alleles. This revealed to be useful in some cases.

The probability of identity (based on genotypes from marked bears in Sweden) using those 5 markers instead of 6 was 1.97 E-05 instead of 7.53 E-08.

Comparison of genotypes

Based on the new calibration keys, the new comparison included 163 different DNA profiles from Norwegian brown bear individuals (see methods), The individuals included in the comparison were from the following counties: Troms (27), Nordland (9), Nord Trøndelag (46), Sør Trøndelag (6), Oppland (5) and Hedmark (66). The following individuals registered in Sweden (Nordbotten and Jämtland) and analyzed at Bioforsk Svanhovd were also included: NB1, JL1, JL3, JL4 and NT6/JL5 (ID name in both Norway and Sweden).

Table 2 shows the results of the comparison and raw data is shown in appendix 2.

Table 2: Comparison of individuals/samples analyzed at Bioforsk Svanhovd and LECA. Samples analyzed at Bioforsk Svanhovd are in bold (ID name) and samples from LECA are sample-ID, not Individual-name. 1=male, 2=female.

For 42 of the 163 DNA profiles of Norwegian individuals there was a match with DNA profiles of between 1 and up to 12 different DNA profiles samples collected in Sweden (see Table 2). In conclusion, a total of 42 of 163 Norwegian brown bears could be found among samples collected in Sweden during approximately the same time period. The 10 individuals identified in the comparison from 2006 (Poillot et al., Report from Laboratoire d'Ecologie Alpine, April 2008), were also recovered in this new comparison, except from NT6/JL5 (see below).

Individuals ST7, HE11, HE20 and HE32 were ambiguous; they matched more than one individual id in the Swedish database (Appendix 2). We considered field data and genotyping data to find the correct matching.

Marker MU59 failed to give a consistent calibration key, and additional analyses are therefore necessary to solve the problems with this marker. We recommend performing a new comparison when this is sorted out. When the genotypes will be completed with this missing locus, there is a slight chance that some current matches between Norwegian and Swedish genotypes might be discarded. The calculation of probability of identity (PI) shows a relatively radical drop when this marker is excluded in the comparison. There are about 2 chances out of 100.000 between unrelated individuals to get an identical genotype without MU59, instead of 7.5 chances out of 100 mill with MU59.

The script output file gave match for five Norwegians individuals (NT6/JL5, TR6, NO8, HE50 and HE42). These five Norwegian individuals matched single samples in the Swedish database with missing data for one marker in addition to MU59 (Appendix 2), i.e. the matches were based on only four markers. Therefore the matches were excluded in the post-treatment of the output. A new comparison with a functional MU59 may confirm the match.

The script output file gave a match between one (HE29/WO424) of the two known individuals analyzed at both labs. WO413 and HE59 gave no match because WO413 has only 3 genotyped markers and therefore don't fill the criteria for match (see methods). However, these 3 markers gave same genotype as HE59.

5. Conclusions

The calibration keys between LECA and Bioforsk Svanhovd calculated in 2008 was recalculated based on an internal calibration done by LECA in 2009. A new comparison between Swedish and Norwegian brown bear genotypes gave 42 matches.

Marker MU59 does not function well in this calibration and additional analyses will be performed to solve the problem with this marker. We recommend performing a new comparison when this is sorted out.

Appendix 2

Raw data from the comparison of individuals / samples analyzed at Bioforsk Svanhovd and LECA. Samples analyzed at Bioforsk Svanhovd are in bold (ID name) and samples from LECA are sample-ID, not Individual-name. Problematic MU59 alleles for Norwegian bears were set to missing data, 0 (except alleles 94, 96 and 108) before performing the comparison of genotypes. Possible alleles were filled in manually after running the script.

Sex column: 1=male, 2=female.

Sample type column: 1=feces 5=tissue

Numbers in red: mismatch or missing data

Numbers in bold: possible alleles for Mu59 filled in manually after running the script

Ind_id in red: excluded ambiguous matches
